L03 Reflection Journal

Coding Methods:

Initially, I would have typed 50 '=' as a border between headline and information/details, however, rather than doing that; typing 'print('=' * 50)' simplifies the task and saves us time. I am familiar with loops, not complex ones, but the basics, and seeing that for the loop under Part 6 doesn't the loop in 'else', is very interesting since for previous assignments I was expected to write 'else' with an action after it. I assumed there's no type of error for the loop in that lab since there are many 'elif' statements. However, 'else' is not needed because the loop found a way to exit through the 'elif' statements, not because of quantity but because of the exits that were provided.

Models:

I was not familiar with different types of models under supervised, unsupervised, and reinforced. I just assumed that the models mentioned previously were the only ways to train a machine, not that there were more specific models. In this lab, I learned more about two specific learning algorithms, logistic regression and decision tree models. At first, I was struggling to understand what made the logistic regression model perform better than the original model (decision tree model), for me both were very similar. However, compared to lab 2, the dataset we're working

on is more complex. Learning to distinguish why one could be better than the other in this specific dataset is important. The decision tree model, when working with complex datasets, the model takes in everything, no matter if it is irrelevant and will make a branch based on irrelevant data it may have and get an unreliable prediction. This allowed me to understand the limitations that decision trees have in this situation. I am aware they are useful and effective but against a better performing model with lots of data, it is at a disadvantage for properly training a machine.
